

05 Try using lighter apps

Presently, a lot of apps have a lighter version available, such as - Facebook Lite, Twitter Lite, Instagram Lite etc. So, how are these apps helpful? These apps consume much less amount of data and storage than their parent app and also the pressure on the hardware while running the lite version is also on the lower side. It directly just gives you more space to run your phone smoothly and not use a lot of space like their beefier cousins.

06 Install apps from proper sources

Always install apps on your smartphones from the official app stores. Never even consider installing apps from unknown sources, especially if a link is provided. Clicking on some random link to install an app or from any unknown sources won't result in anything but just harm your smartphone. Clicking on such links can lead to your data getting stolen or your device getting hacked. It is a massive risk for you and your device's health.

07 Avoid animations

Too much movement of unnecessary widgets and screens just to make it look fancy would just drain your phone's speed and battery. So, it's best to avoid animations on your phone as much as possible. To put all animations to rest on your phone you need to enable the Developer options. First, go to your phone's settings, then move on to about phone, then the build number is required to be tapped seven times. Only then the Developer option will be enabled. Once your animations are off, you will directly feel the change it brings to your smartphone.

08 Delete ancient chats and media

If you have been using a phone for quite some time now, you must have gathered a lot of messages over the years. Be it WhatsApp, default messaging app or any kind of messenger apps. They store

the data on your phone and it simply bloats your phone and uses up storage leading to your phone slowing down. Not only chats, but media files received over the messaging apps also clutter the memory. The solution is simple but a little time consuming. You'll have to sit and manually delete all the old chats and media files which you do not require at all and have just been lying around in your phone eating up the space.

09 A custom ROM?

If you have a slightly old smartphone that might never receive any OS updates hereafter then you definitely require a ROM. This will automatically boost the performance of your smartphone. Choosing a custom ROM is the best option, as then you can select the one which won't include any bloatware but will supply a handful of customisation options. For this you will have to further research a little based on the smartphone you own, as an improper ROM install on your device that it can leave it unusable.

10 Battery optimisation

A smartphone is nothing without its battery. When you use a phone over the years you will eventually realise that the battery doesn't last as long as it used to. So, there are certain things to be done to protect the battery life. Some of which would be - Don't let your battery come down to 0% or go up to 100%, turn off WiFi or Bluetooth when you are not using them, use settings like adaptive refresh rate, enable optimised charging when using a fast charger.

11 RAM management

RAM plays an important role in a device's overall performance. The higher the RAM of your phone, the faster it will be and would make multi-tasking much easier. So, how to preserve your RAM? If your phone is running short on RAM, then there's only one way in which you can make the most of whatever is at hand. Ensure that no apps are running in the background and

every time you are done using an app, make sure that you clear it immediately.

12 Get rid of junk

Malware and viruses may land up on your device from different links and apps. They might not be as rampant of a problem as it was in the yesteryears, but they are still very active and notorious. This is why it mentioned earlier, that no unknown source should be trusted. They just plant malware on your device. Malware and viruses would put your personal data under threat, make your device slow, show unnecessary advertisements, install things in your device without your knowledge. So, in this case you can opt for an antivirus app installation. But as soon as your phone is cleansed, you need to get rid of it, if your phone is known to have a shortage of storage.

13 Granting permissions

Earlier versions of Android didn't have the option to grant permissions for usage of hardware and software level features of a smartphone. But now everything is in the user's hand, for the most part. You can decide as to what permissions you would like to grant your device or any app on your device. Understanding permissions is very important. When your phone asks for certain permission do not just randomly press accept and move on without reading it. Every app doesn't need access to a camera or microphone so be mindful and do not allow them access to such things. This might just breach your privacy and loss of personal and confidential data from your phone. Also, might be a cause of implantation of certain malware. Hence, reading and understanding the permissions are very necessary.

14 Consider web apps

Web Apps or Progressive web Apps (PWAs) are the web version of any app which can be accessed through any browser and will not sit on your phone like other apps and eat up your phone's space. This is another
