

22 TIPS TO SUPERCHARGE YOUR TV

The idiotbox is smart now

Ichha Sharma | feedback@digit.in

Televisions now offer more than just cable content and access to streaming platforms. They are mini PCs on their own. Especially, with sports and entertainment content shifting largely to streaming platforms and the picture quality that they present has led the consumers to invest more in their smart TVs. Manufacturers are also crafting the technology for a wider audience such as the gamers. Having said that, it goes without saying that there are always better settings that you can tweak to enhance your experience.

01 Factory picture mode

Today, every TV has a menu of picture settings, including "vivid," "natural," "sports," and "cinema." Modes with titles like "cinema," "movie," and "expert" typically get the finest results. When a movie is viewed on some TVs

from manufacturers, a function known as Filmmaker Mode automatically adjusts the TV's settings to show films as the directors intended. Although we frequently increase the brightness a little bit because Filmmaker Mode believes you'll be viewing in a very dark room.

02 Adjust Sharpness

In most TVs these days, edge enhancement is controlled by sharpness. Images may appear crisper with this setting, but detail is also lost. Sharpness is by default reduced if you've selected one of your television's pre-set cinema or movie modes. You can adjust this option on your own.

03 Reduce Noise

Film grain, artefacts, and pixelation are all examples of noise. While noise reduction might improve picture clarity, it also washes away details,

giving the impression that everything on the screen is mushy and artificial. Disable noise reduction if you're watching high-definition or 4K. If you leave it on, you can miss out on subtler textures and nuances.

04 Smooth or blur?

Depending on the manufacturer of your TV, you may find this setting under a different name, but the function is the same. By artificially adding frames, motion smoothing makes an attempt to smoothen moving visuals. To get to higher refresh rates, your TV will add frames when motion smoothing is turned on to bring the image up to par. Motion smoothing can cause lag when used in video games. It's recommended to completely turn off motion smoothing in almost all circumstances.

05 Use game mode

For all the gamers out there, if you are by any chance experience input lag try to shift the system to Game Mode for a better experience. Now what is Input lag? This term refers to the time taken between the press of the button and the character or any visual element to move is considerably more resulting in a bad responsive experience from the television's end.

06 Use HGiG Mode for tone mapping

There's a new kid on the block - HGiG integration. It is an extension of HDR. HGiG stands for HDR Gaming Interest Group and aims at making the gaming experience seamless and effective. HGiG works on tone mapping the contrast and colours of the TV system. It helps as a mediator that balances out the calibration of the television output with consideration to the gaming console rendering the optimum visual output. However, HGiG is not available in all the television sets, especially the older models.

07 Turn off power saving

It goes without saying that Power Saving/Energy Saving Mode, as the title suggests, helps you save the energy.
