

3 Blockchain can't be hacked

Although blockchain technology is often touted as “unhackable” because of its decentralized and immutable nature, it’s not entirely invincible. If a single entity controls more than 50 per cent of a network’s mining hash rate or computing power, they could potentially disrupt the blockchain. This is called a 51 per cent attack. Blockchains like Ethereum allow for the deployment of smart contracts. However, if the smart contract is not written securely, it can be exploited. For instance, in the DAO (Decentralized Autonomous Organization) hack in 2016, an exploit in the DAO smart contract on Ethereum, caused a loss of over \$60 million in Ether.

4 “Deep web” and “dark web” are the same

These terms are often used interchangeably, which is wrong, as they refer to two different things. The deep web refers to all parts of the internet not indexed by search engines like Google or Bing, which includes mundane things like private databases, restricted forums and paid content. The dark web is a small part of the deep web that is intentionally hidden from traditional web browsers (like Chrome, Safari, Edge) and can only be accessed with specific software. There are multiple instances of users on internet forums claiming to have accessed the “dark web” when they actually were in the “deep web”.

5 WhatsApp listens to your conversations

While privacy concerns exist regarding data collection and usage by tech companies, the myth of WhatsApp and Facebook actively listening to user conversations lacks substantial evidence. WhatsApp, employs end-to-end encryption for its messages. Both WhatsApp and Facebook have privacy policies in place that outline how user data is handled, typically based on user interactions such as likes, shares, and preferences – not reading or listening to content of conversations. From a technical infrastructure standpoint, actively listening to conversations would be an immense challenges, not to mention a whole different level of legal and ethical concerns.

6 Phone charges faster on airplane mode

The belief that using airplane mode on your phone can charge it faster is a tech myth that has circulated for some time. Airplane mode is a feature designed to disable wireless connectivity on devices, having no direct impact on the charging speed of your phone – disabling wireless features may reduce power consumption slightly, but the impact on charging speed is negligible. Charging a phone involves transferring electrical energy from the charger to the phone’s battery. The charging speed primarily depends on the power output of the charger, the charging circuitry of the phone, and the battery’s capacity.
