

7 AI will replace all jobs

While AI has the potential to automate certain tasks and reshape industries, the idea of total job replacement is unrealistic. AI is best viewed as a tool that complements human capabilities, rather than a complete replacement for human labour. Yes, AI can lead to job displacement in certain industries, but history has shown that technology-driven shifts in the job market often result in the creation of new roles and opportunities. Some industries have already witnessed the integration of AI without widespread job loss. The impact of AI on the job market will vary across industries and job roles.

8 iPhones are more secure than Android

The belief that iPhones are completely immune to malware is a tech myth that has been perpetuated, but it is not accurate. While iPhones do have robust security measures in place, they are not impervious to malware. Despite being relatively rare compared to Android, instances of iPhone malware have been reported like the XcodeGhost malware in 2015, which infected numerous legitimate apps on the App Store, and the Pegasus spyware discovered in 2016, which exploited vulnerabilities in iOS to target and spy on specific individuals. Jailbreaking iPhones can introduce security vulnerabilities and make it more susceptible to malware.

9 Ejecting USB drives always necessary

While it's generally a good practice to safely eject USB drives before physically removing them, modern operating systems implement write caching to minimize data loss. This means as long as there is no active file transfer or writing operation, removing the USB drive is usually safe. But there are instances when you can have a background process using the drive. So, it is sort of a better safe than sorry measure to remove the drive. It is not compulsory in 99 out of 100 instances as long as a file transfer instance is not active on your system!

10 Keeping your phone or laptop plugged in damages its battery

Modern smartphones and laptops are designed to handle being plugged in for extended periods. Once the battery reaches 100 per cent, the charging process stops, and the phone and laptop runs on AC power. This is applicable to most modern smartphones and laptops. We'd recommend to read up on your device's specifications and ensure that you are not working with a device that does not support the power hand-over. However, it's recommended to occasionally discharge the battery to maintain its health and overall longevity.
