

measured and offset actively. The customer also gets an option to operate the devices as net zero.

Q How have users responded to MKII? Could you share any feedback you've received from your pre-order customers?

A There's a lot of surprise - most didn't think filterless purification was possible. Some who couldn't visit our demos at the Mumbai office would often wonder if there's something suspicious happening when we sent them the videos. But when we'd take the device to their factory and show them how it worked and they could see the dust getting collected, there was a sense of awe. I think Indian customers are not yet risk taking, so it would take us time to get our foot in the door, but wherever we've been able to do so, we've seen positive outcomes - the devices definitely solve customer problems, and we continue to build features which could enhance their experience further!

Q With the successful launch of the MKII, what are Praan's plans for future development? Are there any new features?

A The MKII product is amongst the most exceptional pieces of engineering our team has put out. The device is constantly improving based on the data we collect from its surroundings, and is expected to help customers save a lot of raw material by mining it straight from the air in the factories. We've constantly been improving the customer experience via Over the Air Updates and through a common cluster control software. We also have plans of auto dust collection and auto-dust use, along with future projects within it for fume and greenhouse gas removal.

Q What were the biggest challenges in developing the MKII? Conversely, what would be your greatest achievements during this process?

A Everything about it was really hard - making high flow rate filterless air purification possible in this form factor, being able to safely remove conductive dust without the device catching fire,

Existing Solutions don't solve the problem

Current solutions v/s MK II
De-dusting systems with ESPs/Bag filters, water cannons, or filter-based purifiers which are not cost effective

De-dusting system with ESP/Bag Filter	Water Sprinkler	Filter-based Air Purifier	Praan MK II
			
Needs new infrastructure	Needs manual operation	Not designed for manufacturing spaces	No new infrastructure, easy to install and own
High Lead Time	High Lead Time	High Lead Time	Short Lead Time - Plug and Play
Very hard to maintain	Local maintenance only	No on-site maintenance	Complete on-site maintenance
Requires additional filters	Requires large amount of water	Requires constant filter changes	No filter changes needed
High energy consumption	High energy consumption	High energy consumption	Low energy consumption
Not environmentally friendly	Not environmentally friendly	Not environmentally friendly	Highly sustainable
No material reusability	No material reusability	No material reusability	Allows material reusability
No inbuilt reporting	No inbuilt reporting	No inbuilt reporting	Real-time ESG-Reporting
No-net zero	No-net zero	No-net zero	True net-zero
No Over the Air Updates	No Over the Air Updates	No Over the Air Updates	Over the Air Updates

consistently manage sticky dust, build prototypes for this product given the size, handling and manufacturing such a large product as an early-stage startup, delivering and installing the product, and more. Greatest achievements are the ability to capture dust which would otherwise catch fire in these large factories, making the device affordable yet profitable, being able to simulate how pollution flows in such large spaces, making the dust reusable, and actually being able to deploy these devices in such high dust/toxic working conditions.

Q How do you envision Praan's impact on the air purification industry and the broader efforts to combat air pollution?

A Praan is going to be a significant accelerant for the adoption of clean air globally - not just by expanding the industry with new tech, but by establishing a new

benchmark for what it means to build and sell an air purifier, it's software, it's upkeep, and make the ownership aspirational yet common to all.

Q What is your long-term vision for Praan? How do you see the company evolving in the future?

A Praan was always designed with the hope of making the future more hopeful and exciting for the generations to come. Air Pollution mitigation is where we start now - industries, and commercial spaces (with our products being sold to businesses). We will begin manufacturing sensor modules in India next year along with expanding on our Carbon Capture projects more aggressively. Along with tech innovations, we hope to make from India for the world, expanding our sales into other geographies (We've already seen interest from several customers in SEA, EU, and South America). **d**
