

where the bezel's ratcheted action was stuck at half and was accidentally triggered when the watch brushed against my body or sometimes when I was moving my hand as well. The second is automatic activity tracking. There were a couple of instances when I was out for a walk, and the watch recorded a swim. I did not jump into the pool with the watch and was on the sidewalk. I think, especially with the LTE version, the watch should also make smart use of my location data to know whether I am close to a pool or not.

It was not something that happened every time, but if I were to pay for this watch, even a single instance of that happening would irk me. Lastly, in two very distinct instances when I was on a call in an area with good cellular reception, the watch's reception went to zero and the call ended. However, this was when I slid my hand into the pocket of my jeans, and I tried replicating the same thing after the first two times it happened, but I wasn't successful. Maybe it is a one-off, but again, if there's anything that would prevent that, I would love to know. Otherwise, calling and using the cellular connectivity on the watch was a charm!

Now, coming to the good part. Let's start with the activity tracking. It was on point all the time. It did pick up the wrong activity on a couple of occasions as I mentioned before, but for the most part, it was something that impressed me. I pitched the numbers recorded by the Samsung Galaxy Watch 6 Classic against that of my Apple Watch Series 7, and the results were on point all the time. Having used the Apple Watch for some time now, and having walked the same route a fair number of times, I am pretty confident of the metrics of the Apple Watch, that's why the comparison.

The watch was able to handle almost everything that I sent its way. The Samsung Wallet worked when needed, sleep tracking was also accurate almost every single time. There were one or two occasions when I did feel that it was off by like 10-15 minutes, but that I guess, can be attributed to a whole lot

of factors which come into the picture when you are asleep. The BIA analysis was something that I personally had never experienced on a watch before. I did not have any way to verify the readings taken by the watch, but from what I knew from my historical medical data, the watch did a good job.

Lastly, in terms of battery life, on a day of regular use, with inconsistent cellular reception, the Samsung Galaxy Watch 6 Classic lasted through my workday, with me needing to juice it up at the end of every day.

Does it hold up against the heavy hitters?

In the Android space, there are very few watches that come close to Samsung's lineup in terms of their capabilities and pricing as well. If you are a hardcore fitness enthusiast, then you might look at a Garmin watch, which would cost a bomb. Fitbit is not as charming as it used to be,

and other manufacturers are playing the budget game. Apple, which is the brand that comes closest to this, is trapped in its own ecosystem, where it's winning a race that it is running alone. They are doing a good job, but the constraints of the "ecosystem" drag it down when it comes to a market outside of Apple users.

So, if you have the money, and are looking to take the plunge, then I can say you should get your hands on the Samsung Galaxy Watch 6 Classic. It gives you what you would expect from the money you are shelling out for it and more. I believe it is meant for a crowd that would go to office, workout, cook, and want to do everything under the sun with the watch on. And, it nails it! If you are a hardcore fitness enthusiast, then I would say you can look at the Garmin Venu 2 Plus or if you are looking for almost the same specs at a slightly lower price, then you can go with the regular Samsung Galaxy Watch 6.
