Crypto is a waste of time

While promising decentralisation and a global financial revolution, crypto's starting to feel like digital sandcastles. Its extreme volatility makes it a very risky gamble and not at all reliable. What's worse is that many crypto projects offer little beyond speculation, lacking real-world

utility. Plus, security breaches and scams abound, making it a playground for fraudsters. The question you've to ask yourself in the face of all the crypto hype is simple: Is building digital fortunes really worth the time and risk when stable alternatives exist? I don't think so.

20

VR will never become mainstream

While VR has potential in niche areas like gaming and training, its widespread adoption faces significant challenges. VR hardware needs to become more user-friendly and

affordable, the content library needs to mature, and concerns about safe use, accessibility and social impact need to be addressed. Until then, VR might remain a fascinating toy for tech enthusiasts, not a true revolution for the masses. 

21

AI will not replace all human jobs

While AI excels at automation, replacing all human jobs is unlikely. Many professions require creativity, social intelligence, and adaptability, areas where AI still struggles. Think therapists, artists, negotiators - their skills thrive on nuance and human connection. Plus, new jobs will emerge alongside automation, requiring skills like AI management and data analysis. So, instead of fearing replacement, focus on upskilling and embracing the human-AI collaboration shaping the future of work.

22

AI ethics education should be mandatory for all

As AI becomes more prevalent, ethical considerations should be a core part of tech education. The current AI landscape lacks diversity in background, thought, and much needed ethical perspectives and considerations. Voices from different cultures and disciplines are crucial to avoid inherent human bias and ensure equitable AI development now and into the future.

23

Overdependence on AI will diminish human intelligence

When AI readily solves problems or provides information, our own problem-solving skills and critical thinking abilities can weaken through lack of use. Just like any muscle, they need regular exercise to stay strong. Another thing to consider is relying on AI for factual recall and quick information access decreases our own memory capacity and the need to actively learn and retain information. This can hinder long-term knowledge acquisition and understanding. And when AI starts generating ideas or completes tasks in an automated way, our own creative thinking and problem-solving approaches can become limited. We lose the chance to explore, experiment, and develop novel solutions. Beware what you wish for!

24

AI alone won't solve humanity's problems

For all its brilliance, AI is only a tool. Solving humanity's biggest problems like climate change, inequality, and social conflict require more than algorithms. They demand empathy, ethical judgement, and collective action. AI can help analyse data, optimise solutions, even create art, but it lacks the moral compass and understanding of lived experience needed to truly "solve" these complex challenges. Remember, technology alone can't build a better world; it's our choices and actions that will steer the course.
