Buying audio is something that you as a consumer, have a lot of say in. As a guide, we can give you a host of pointers. However, at the end of the day, what you hear and like, is what would define a good audio experience for you. So, before getting started with anything, I would like to suggest you, whatever product you choose, make sure you listen to it once before going ahead with the purchase. With that out of the way, let's get started with this guide to buying headphones and earphones –

Higher doesn't always mean better

When selecting headphones, the number of drivers doesn't necessarily indicate superior sound quality. Sound frequencies are divided into lows, mids, and highs, each generating a unique vibration pattern through the driver. Multiple drivers in earphones share the workload, but precise tuning is essential to ensure accurate handling of designated frequency ranges. Improper tuning may result in loud but inaccurate audio. To assess this, test

earphones with a frequency sweep covering the entire audio spectrum (20Hz to 20,000kHz).

Tuning takes precedence

Tuning involves calibrating drivers to accentuate specific frequencies. Manufacturers may tune their drivers differently, prioritising various aspects

of sound and creating diverse sound signatures. For instance, some headphones emphasise bass, while others produce a V or U-shaped sound with boosted lows and highs. Even drivers with identical specifications can sound distinct if not precisely tuned. Studio-grade and consumer-grade headphones from the same brand
