

in-picture, it is limited to just a few apps like Netflix, Amazon Prime, or FaceTime that have native support for it.

PRIVACY AND SECURITY

Coming to security, which is undoubtedly one of the most important aspects of the digital age we live in, iOS here trumps Android by a margin for multiple reasons. First, the App Tracking Transparency feature which asks iOS users if they want an app to track them across the internet each time they download an app. Now, while Android also has the option to hide your advertising ID from third party developers and websites, it doesn't always prompt you if you want a certain app to track you across the internet or not. You can, of course, switch it off from the settings (Settings > Privacy > Advanced > Ads > Opt out of Ads Personalisation).

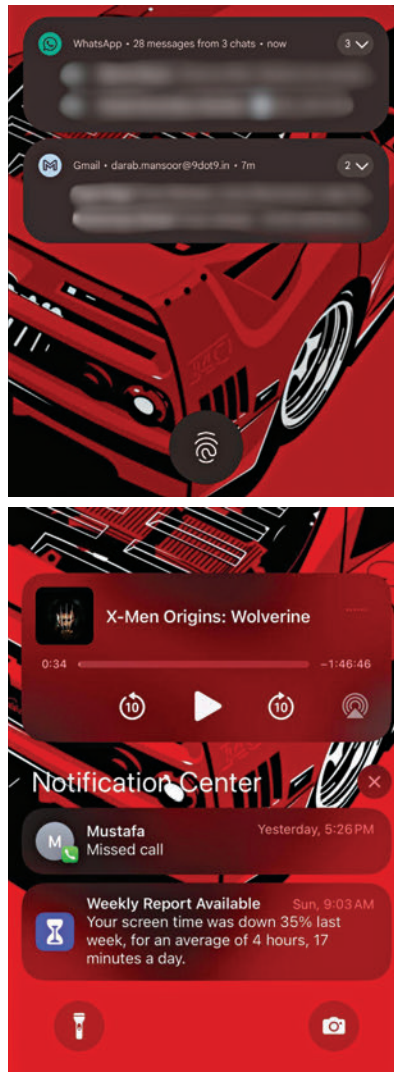

Not only this, iOS is also considered safer since it is a more closed operating system as compared to Android's open nature. The Android operating system can be installed on a wide range of devices, as compared to Apple's inseparable design.

One thing that some Android manufacturers do better is offering on-device storage of sensitive data. For example Google's Titan chip or Samsung's Knox or even Motorola's Think Shield protocol ensure that all your sensitive data like passwords, PINs and more are stored directly on the device and not on any cloud or server.

NOTIFICATIONS

Now, the third thing that I believe keeps making me coming back to Android is notifications. We don't usually notice but the way Android and iOS send you notifications has both its perks and disadvantages at the same time and both are completely different. While the idea behind notifications in both is similar - to not only notify the user, but also give an option to expand, respond, or even possibly turn off or mute notifications.

But why does Android do it better? First and foremost - having everything

in one place, barring a few exceptions. For example, in iOS, you have to pull from the top right of the screen to get the control center, and pull left from the top to access notifications. For most Android smartphones, can pull from any side of the screen and will get both notifications and quick settings in the same place.

Further, quick replies. On Android, you can reply to messages on WhatsApp, Instagram, and other apps directly from the notifications panel. However, on iOS you can only do that the moment you receive the text. Android, in fact, even allows users to reply quickly to their messages even from the lock screen without having to unlock their smartphones and opening the app.

Second, notifications stacking. On iPhone, the stacking is done in a very simple and linear manner. The notifications are stacked one after the other, unless it is from the same chat in the same app. On Android, messages are collated based on apps and not chats. For example, an Android smartphone will show you "7 messages from 3 chats" on the panel for you to tap or drag on this to reveal the text. On Apple, things just get stacked one after the other.

Lastly, just the sheer amount of options and customisations that are available on Android just make Android better in this aspect. On Android smartphones, there are many options within the settings also that allow users to adjust notifications on each app, notification style, how much content you'd like your notifications to reveal, what notifications you want to see first, floating notifications, and Android also allows users to see their Notification History. On iOS, on the other hand, the only settings you have is to adjust how notifications are seen on your lock screen (Count, Stack, or List), scheduled summary, show preview, and then a list of apps for you to turn notifications on and off as per your preference.

The only thing iOS does better with notifications is the summarisation. Users can summarise all notifications from an app for a given time period so you can go to them the moment you have time to go through everything from a certain app. Would be really helpful for that Instagram addiction most people are suffering from.

So that was a quick comparison of three very important things that concern people in their day-to-day smartphone usage. Now, there is no better or worse here. While Android offers a lot more customisation or flexibility options, a lot of people prefer the seamless and more straightforward approach of iOS. Yes, in terms of privacy Apple offers better security mainly because of the closed nature of the operating system, but Android has also become much more secure in the last few years. **[d]**
