

techniques, including transformer-based Deep Neural Network models, to accurately identify and notify users when audio in a video is likely AI-generated or manipulated. Demonstrated at RSA 2024, this collaboration showcases significant performance and privacy improvements made possible through Intel's AI-powered PC technology.

By leveraging the Intel Core Ultra processor's NPU, McAfee's AI models can perform inference—analysing and detecting deepfakes – locally on the device without sending private user information to the cloud. This local execution has led to a remarkable 300% performance improvement on the same model. The enhanced performance, combined with the privacy benefits of local processing and improved battery life, offers substantial advantages to customers. This collaboration ensures that consumers can benefit from real-time, efficient, and secure deepfake detection directly on their devices, enhancing their protection against sophisticated AI-driven threats.

millions of customers around the world from the threats of today and tomorrow. Legislation and regulations that curb the harmful use of AI will provide another vital step in the broader solution. In February 2024, McAfee joined leading tech companies such as Adobe, Google, IBM, Meta, Microsoft, and TikTok to play our part in protecting elections and the electoral process, as part of the Tech Accord to Combat Deceptive Use of AI in 2024 Elections.

In doing so, we've pledged to help prevent deceptive AI content from inter-

research and investment in developing and deploying precautions to limit the risks of malicious deepfakes, attaching a record of the origin of content when possible, working to detect deceptive content, responding quickly and proportionately to the creation and dissemination of malicious deepfake content, participating in collective efforts to evaluate and learn from efforts to detect and mitigate deepfakes, engaging in shared public awareness and education efforts, and participating in initiatives designed to protect information integrity.

Q How will McAfee measure the success of its deepfake protection initiatives?

A McAfee's Deepfake Detector utilises advanced AI detection models to identify AI-generated audio within videos, helping people understand their digital world and assess the authenticity of content. Much like a weather forecast indicating a 70% chance of rain helps you plan your day, this technology equips consumers with insights to make educated decisions about whether content is what it appears to be. We see success as giving users the clarity and confidence to navigate the nuances of our new AI-driven world, to protect their online privacy and identity, and their well-being.

Q What role do you see regulation and industry standards playing in mitigating AI deepfake threats?

A McAfee is focused on educating consumers about the evolving threat landscape, and designing, building and delivering innovative solutions that protect

fering with this year's global elections by bringing our respective powers to bear, to combat deepfakes and other harmful uses of AI. That includes digital content such as AI-generated audio, video, and images that deceptively fake or alter the appearance, voice, or actions of political candidates, election officials, and other figures in democratic elections. Likewise, it further covers content that provides false info about when, where, and how people can cast their vote.

Q Deepfakes can be easily created and distributed online. How can collaboration between cybersecurity firms and international law enforcement agencies be improved to tackle this threat?

A We see collaboration between cybersecurity firms and government agencies as essential for tackling online threats such as deepfakes. By sharing knowledge, resources, and expertise, we can collectively mitigate the risks posed by this evolving threat. This includes

Q Any unique challenges India faces with AI deepfakes compared to other regions? How is McAfee adapting its approach to address these challenges?

A India has 820 million active internet users, and the combination of low latency and widespread access to millions of smartphones and social media accounts means that content can go viral quickly, potentially causing irreparable damage to the dignity or image of individuals. As technology evolves, so does this battle – not just for India but for the whole world. The advent of the latest digital technologies marks a decidedly new era in this struggle. Scammers across the globe employ new methods of trickery in different corners of the world, often AI-powered, to work around existing protections. Meanwhile, security professionals are creating technological advances to counter and prevent these attacks. **[d]**
