

Dolby Vision FAQs

Now that we have explained what Dolby Vision is, let's address some Dolby Vision FAQs

Q What is the difference between TV-led Dolby Vision (Standard mode) and player-led Dolby Vision (Low latency DV)?

A In player-led Dolby Vision (Low Latency DV), the source device (such as a Blu-ray player or streaming device) handles the Dolby Vision processing instead of the TV. In TV-led or display-led Dolby Vision (Standard mode), the TV processes the Dolby Vision content, which is typically said to result in a better viewing experience.

TV OEMs and Dolby often do not specify which type of Dolby Vision processing is supported on specific TV models. However, for most practical purposes this should not make a major difference if you have purchased your Dolby Vision TV in the last few years since your TV will have support for the new Low Latency DV format.

Q Is Dolby Vision content supported on Social Media Apps?

A Some social media apps allow consumers to upload and view Dolby Vision content on compatible devices. These include Vimeo and Moj in India, and Bilibili and Weibo in China.

Q Do Dolby Vision TVs require calibration?

A Yes, it is a myth that Dolby Vision being an end-to-end solution makes adjustments for TV calibration. For the best experience, you will need to calibrate your TV.

Q Is Dolby Vision on Blu-rays better than Dolby Vision on streaming services and OTT apps?

A Yes, Dolby Vision on Blu-rays offers a much higher bitrate and thus offers higher quality.

Q What about Dolby Vision content created on iPhones and Android phones?

A Dolby Vision content created on iPhones and a few compatible Android smartphones is based on Profile 8.4 designed for direct distribution and playback. Profile 8.4 has HLG as the base layer instead of HDR10 which uses a slightly different transfer function than PQ or SMPTE ST 2084 which is designed to be compatible with both SDR and HDR displays and is thus highly backward compatible.

Q What are different Dolby Vision Profiles?

A Dolby Vision profiles describe the video codec and set of coding techniques used to encode a Dolby Vision video. Consumers don't really have to bother with what Dolby Vision profile is being used.

The latest is Dolby Vision Profile 20 which is used to generate 3D Stereoscopic Dolby Vision videos for AR/VR headsets.

premium features that enable TV manufacturers) to differentiate their high-end offerings into a different tier. It adds some intelligent features that can help the TV stay true to the creator's intent even with changes in room lighting.

This is needed because HDR Content is mastered in a dark room and is meant to be viewed in a dark room with an ambient brightness of 5 nits or lower for the most accurate representation. However, in practice, most people use their TVs in well-lit living rooms and in such lighting our eyes can not catch all fine dark details.

Dolby Vision IQ offers two new features - Light Sense and Automatic Playback Optimization. As the name suggests Light Sense analyses data from the TV's ambient light sensor and Dolby Vision metadata to optimize HDR experience according to the changing ambient lighting.

Automatic Playback Optimization allows content creators to tag their content type via L11 metadata. The content can be marked as Default, Movies, Game, Sport, or User Generated Content. This information is then used to optimize factors such as white point, frame rate, noise reduction and sharpness according to the content type.

For example, "Movie" content requires minimal post-processing, while "User-Generated Content" can benefit from more extensive processing to overcome consumer camera limitations. If your TV does not support Dolby Vision IQ technology, the new L11 content type metadata will be disregarded. Samsung's answer to Dolby Vision IQ was HDR10+ Adaptive which makes similar adjustments to HDR tone mapping based on ambient room lighting. **d**

scarce. There are a few other differences too, like Dolby Vision supports 12-bit colour and is not royalty-free, unlike other popular HDR formats like HDR10, HDR10+ and HLG. Also, all Dolby Vision content comes with a base HDR10 layer as well. If your TV

doesn't support Dolby Vision, it can pick MAXCLL and MAXFLL values from Dolby Vision Metadata and then play the content as HDR10.
