

Makers are basically tinkerers who fiddle with everyday things to create innovative products using technology. They can be called the DIY guys of the tech world. Makers are aligned to engineering-oriented activities such as electronics, robotics, 3D printing and metal/wood-working.

Let's look at an example. Say there's an increase in the temperature of your room. Ideally, an air conditioner would reduce the temperature. At night, however, a better way to manage this situation would be to let the cold air outside if it's at a lower temperature and then cool the room further if necessary. This sort of logic is what the future devices will be capable of. Also continuous air conditioner use will increase the level of carbon-dioxide in the air. These devices will monitor the level of carbon-dioxide and let fresh air into the room, if necessary. Believe it or not, someone has

actually created a fart detector that will sense the obnoxious smell and let some fresh air into your house or office.

The Arduino™ platform connected to appropriate sensors and driven by appropriate logic can help build the Internet of Things. The 'logic' here is the program that the micro-controller in the Arduino™ platform will execute.

Wi-Fi shield to connect to internet

To sum it up...

The future is all about billions of sensors sensing the environment and taking decisions with or without very little human intervention. These devices will continuously adapt to changing conditions to find better ways to manage and better utilise new conditions. Makers are the people who are expected to play a role in the creation of this revolution.
