

Bluetooth

If you want to wirelessly control your device using a cell phone on which an appropriate app is installed or via a computer with Bluetooth device, the Arduino™ BT is the most suitable board.

USB Host Functionality

Arduino™ Due has two USB ports:

1. Programming USB port
2. Native USB port

The Native USB port on this board is directly connected to the ARM processor and will let you connect peripherals such as keyboard, mouse and smartphones.

Arduino™ Yún also has USB host functionality support.

SD Card / Wi-Fi

Arduino™ Yún has SD card support and Wi-Fi support. If you need more pins, go for Arduino™ Mega ADK or Mega 2560 with an appropriate shield.

Processor speed

The speeds mentioned in the table ‘List of Available Arduino™ Boards’ seem very low compared to that of a personal computer, but these devices don’t carry out heavy computation. So don’t be tempted to get the 84 MHz Arduino™ Due for its higher speed. You’ll observe that most of them perform tasks with equal speed.

In case you need more computing power, say, for statistical calculations or video-related tasks, there are newer processors that can help. You’ll find details of such boards in the chapter on Advanced Hardware. The speed of processor also needs to be considered when a large number of devices are connected to the microcontroller. For most applications, an 8 MHz microcontroller will suffice.
