

The board has an SD card slot.

All critical information can be transmitted using the XBee module. While experimenting, however, it could happen that your device generates a large amount of data that can't all be transmitted using XBee.

In such a case, the best way to retain data of live operation is to save it on the SD card. This card can then be plugged into a computer to retain the data and perform further analysis.

Arduino™ Wireless SD Shield

The shield can also be used as a mini Proto Shield.

The above given list of shields have libraries that allow easy programming of the components on the shield. The best thing about using these add-on boards is that multiple shields can be stacked on top of each other, allowing you to have multiple functionalities simultaneously.

In this chapter, we looked at an Arduino™ add-on hardware called Shield that increases the possibilities of using the Arduino™ for various purposes while maintaining the inherent simplicity of the Arduino™ platform. We looked at shields that can help connect motors, use GSM network, connect to Wi-Fi network and use an SD card. With sufficient knowledge, you would also soon be able to make a shield of your own.

If you are unable to find a shield for your use, it is possible to make your own shield and share it for everyone to use. All you need is some knowledge with PCB design. You can check the guide at <http://dgit.in/mkursbiel>.
