

You are the next gen creator

The ability to create future devices is what makes the field of electronics so exciting.

Most of us were first introduced to the world of electronics when a TV repairman came over to repair our broken TV. We'd see him tinker with some black things (the chips), some round things (resistors and capacitors), some wires joining everything placed on a board (circuit board), and a device to check whether everything was working (voltmeter). It all seemed very complicated.

We've come a long way since then. Technology is getting much more sophisticated, and soon electronic devices will be embedded into our clothes. Such electronics devices are easier to build today and the process will only get simpler. The internet has augmented progress on this front by enabling anyone with a will to create almost anything they put their mind to. Though the common man still can't build a TV by himself, there are many more exciting things that we can build using our existing knowledge of electronics.

This FastTrack introduces you to a platform called 'Arduino™' that has completely taken the world of electronics design by storm by giving the power of creating technology into the hands of not just adults but also kids, in a very cost effective way to boot. So if not you, it might help the creative young'uns in your home or neighbourhood to utilise their free time more creatively.

This booklet can be used by beginners as well as experts. Beginners would do well by reading the book from cover to cover for a working know-how of the Arduino™ platform. While the experts might want to skip most sections, we have a Chapter 7 highlighting a few projects you may be interested in working on. People who are familiar with microcontrollers buy unaware about Arduino can skip to Chapter 3 directly. We recommend everyone to read the last chapter, 'Primer to Electronics'.
