

Quadcopter implemented using Arduino™

is called a ‘Quadcopter’. Research groups and enthusiasts that work on projects like DIY drones around the world use the Arduino™ board as a platform to build such advanced aerial vehicles.

To make a quadcopter, you’ll need the following components:

- ◆ Brushless DC motor
- ◆ Motor driver
- ◆ Arduino™ board
- ◆ Inertial Measurement Unit (IMU) (which combines a gyroscope and an accelerometer)

You can check the link <http://dgit.in/quad.Arduino> for more information.

To conclude...

This chapter kicked off with the basics of sensors and a brief explanation of how the real world interacts with computers via sensors and actuators to carry out tasks. Then, you learnt of the different types of sensors around and their areas of applications with a few examples of each. Now that you’re aware of the types of practicable Arduino™ projects – right from an automatic garden watering system (inspiration from the first chapter) to an autonomous wheeled robot and persistence of vision wand, moving all the way up to research unmanned aerial vehicles, namely, quadcopters – you can get started with your first project. There are many interesting projects on the internet to fire up the creative genius in you.
