

You arrived at the decision not simply based on some arbitrary perception of what should be done, but based on the surrounding environment (temperature, humidity, soil moisture, etc.) and the amount of water in the water tank.

How did you get all this information?

You had various sensors installed to automate parts of your home: a water sensor to pump water into the overhead tank, soil moisture sensor to check for low moisture condition, temperature and humidity sensor to keep your home at comfortable temperature and moisture level. Also, the email had an in-built time stamp that helped to decide on the time left for sunset. You programmed your home to send all the necessary data for you to be able to take an informed decision.

It's also possible to automate the decision-making part and inform you about the decision taken. You could then either modify the automatically taken decision or let it happen.

Scenario 2

You're on your way home and, let's say, 30 minutes away from reaching there. Leaving the AC on all day will lead to power wastage. So you send the following email:

To: bome@bivemind.in

From: me

Time: 7:20:39 PM

Subject: AC

Body:

Home: Reaching in 30 minutes

AC: 26°C after 30 minutes

You get this reply:

To: me

From: bome@bivemind.in

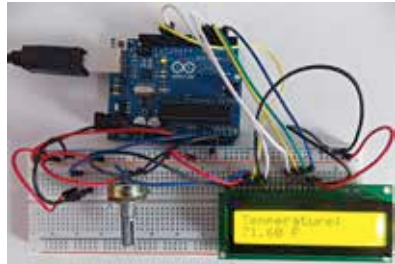

Time: 7:21:45 PM

Subject: Re: AC

Body:

Home: Your parents will reach in 45 minutes

AC: Parents' request for 28°C in 45 minutes

Hardware to sense current temperature
