

applications that can be used to test mobile applications on” instead to be more accurate?

Both VirtualBox and Bochs can create an x86 virtual machine to run an operating system and software on, however what VirtualBox does is virtualisation, while what Bochs does is emulation. There is a good reason why there is a distinction, but bring overly pedantic about it isn't helpful unless one is actually developing an emulator / simulator or hypervisor themselves or working in depth with one.

There is a balance to be struck between technical accuracy and just getting the point across. We aim to strike a good balance.
