

ART or Android Runtime is what runs apps on Android. It replaced Dalvik and a something similar is going to be running your apps on Chrome. Compatible with Chrome 37 and beyond, ARC or App Runtime for Chrome is the run time that lets you use android apps on Google's Chrome

Android with a Heart of Chrome

OS. While the original run time isn't compatible with any other OS, developer vladikoff developed the ARChron Custom Runtime while lets these apps run on Windows, OS X and Linux.

Start by downloading and unpacking ARChon Custom Runtime and enabling developer options in Chrome by hitting Menu > More Tools > Extensions. Click "Load unpacked extension" and select the folder where you unpacked ARC. Ignore the warnings and you're done with the easier first step.

Step two involves finding Chrome APKs. While there is an entire subreddit for this--/r/chromeapks--we should warn you that using them is an infringement of copyright laws, and if you're getting a modified paid app, it's piracy and ye'd be a scurvy dog for doing so.

Once you've identified the modified app that's available free of cost at the Google Play store, all you have to do is unpack it and add it to Chrome the same way you added ARChon Custom Runtime. Your app is ready and you can Whatsapp people from the comfort of your PC.

Manymo

Aimed primarily at app developers, Manymo is an online Android emulator that lets users test their apps on many mobile phones (oh, that explains it) without having to resort to begging/borrowing/stealing. While the the word 'many' is still loosely defined, Manymo allows you to launch your app on a version of Android as recent as Android KitKat, you can also launch the app on a variety of displays ranging from 720p tablets to tiny 320p displays.
