

OSFmount lets you mount images as removable or fixed hard drives, CDROMs or as a floppy.

unless you save the data back to an image or copy it out.

Another interesting tool of this kind is Pismo file mount. This clever utility happens to be one of the easiest to use systems for mounting files. Rather than pop up a new drive letter — which it can also do by the way —

OSFMount can mount image files as optical drives, Hard drives or even floppy drives. It can also mount image files as removable media (such as USB drives).

One of the interesting features it has that you will undoubtedly find useful — some day if not now — is its ability to create RAM drives. A RAM drive is a just like any other virtual hard drive, but with its data stored in RAM instead of a file. RAM being from a hundred to a hundred thousand times faster than the average hard disk this basically gives you a super-fast hard drive that you can use for hardware intensive processing, such as compiling software etc. Beware that the data is lost on reboot

Pismo file mount instead just makes it appear as if the disk image is a folder. So if you have an image file at “D:\myimage.pfo”, when you mount this image using Pismo, you will suddenly see this convert to a folder “D:\myimage.pfo\” that you can open and copy files in and out of. When you unmount it it goes back to being a file. Pismo can also compress or encrypt these files if you so

Pismo file mount has one of the most clever implementations of mounting image files.
