

Virtual Display Manager supports many different configurations for virtual displays.

as far as emulating a monitor.

However, there is a use case when it comes to multiple monitors, and this can go two ways. The first is that you have multiple monitors that you have placed in close proximity, and you wish to use them as a single combined virtual monitor. This is easy to achieve on Linux, but not possible by default on Windows. For Windows you might even need to get hardware that splits one monitor feed among multiple screens.

The other more interesting usage is to split a large display into multiple virtual screens, so you can manage a 27" or above display as two or more displays. This has certain advantages, such as individual task bars on each screen, and multiple maximised windows etc.

For this purpose there are a number of applications for Windows, such as Winsplit Revolution, and Virtual Display Manager.

Another interesting usage is Virtual Desktop software. This is

features that you won't find in the above, such as streaming game content, streaming video directly without additional software. And, it is also available for OSX.

## Monitor emulator

Outside of virtual machine software like QEMU, VirtualBox, VMWare, and Hyper-V, such a thing just isn't that popular. It's already easy and possible to route the screen output to a video, and software and pre-process this output without needing to go

Antimicro support creating multiple profiles that automatically activate when the corresponding app is launched.
