

For example, if you wanted to develop multi-touch applications for Windows, but were lacking an actual multi-touch capable display, Multi-Touch Vista is a great free software for just that. It can use multiple connected mice as one combined multi-touch system with each mouse representing a touch point.

Emulating a GPS chipset too can be quite useful, and `gpsfeed+` is a good free tool to do just the same. It can set your virtual location to anywhere in the world, and can even play back a recorded list of locations, to give software the impression of movement.

We have not covered network card emulators, but they are certainly useful especially if you want to test the effect of different network conditions on software; but that a niche concern.

While there is a lot more that can be emulated, but unless you are a developer chances are what we've covered will be enough.
