

EMULATING BROWSERS

You thought only operating systems, gaming consoles and mobile devices can be emulated? You are wrong.

Emulation isn't restricted to operating systems or old school arcade gaming alone. It's also possible to emulate different web browsers. This can be done by recreating the environment of one browser on another. Usually, browsers are emulated for the purpose of cross browser testing.

Not all browsers are created equal. Consider for example Internet Explorer and Mozilla Firefox – both of them have different methods of handling a simple HTML page. Since every browser employs a different rendering engine, a single website could be displayed in many different (possibly unintended) ways. Emulating browsers imitate the way a particular browser renders a web page. With browser emulation, multiple browser installation is avoided. These browser emulators are also used to simulate rendering for mobile devices. With the increasing consumption of data from mobile devices, it has become a necessity to make mobile versions of web pages that are well optimised for the small screens. In addition to knowing how their designs will display on various browsers, web designers can also check out how their sites will render on different types
