

different browsers. Besides supporting various browsers, it also lets you test over multiple operating systems.

Testing is easy, just enter your URL and choose the browsers you require. You can also choose presets such as screen size, color depth, JavaScript, Java and Flash. After submitting, you must wait until the screenshots are ready. The download will start automatically thereafter.

Browserling

Browserling is another free browser emulator powered by Canvas and JavaScript, offering interactive cross-browser testing. There are more than 80 browsers to choose from along with the ability to change the resolution. To test your website, enter its URL, select the browsers and hit run. The only drawback of Browserling is its three-minute limit. Once your test is ready, you have three minutes to review your site in multiple browsers. Browserling demands \$250 (approx. Rs.15,420) per month to remove the three-minute restriction. Along with higher time limit, the paid service also offers SSH tunnels to access local host and intranet services. This means apart from the already hosted website, you can also test the local web pages stored on your computer or made available within the local area network.

In conclusion

Note that not all emulators provide 100 percent accurate results. This makes the task of finding the right emulator tough and time-consuming. These paid services do provide (nearly) accurate results, however the results provided by the free services are open to debate. The accuracy is concerned with the rendering engine alone and not the layout. All the emulators are capable of laying out web pages across different devices perfectly.

Emulators are a neat and handy way to test web pages across different browsers and devices. If, however, you're concerned about the accuracy, don't rely on the emulators and instead use the actual browser. In the case of testing the layout across different devices, emulators are the only option you have.
