

Tool of instant communication

trend coincides with the declining rate of reading, which is replaced by multimedia or social networking activities. Research also shows that the time children spent viewing screens increases with age, from infancy to early teens and then spiking significantly as they approach their teens. Alarming, this period coincides with a noticeable drop in their academic retention in subjects such as math and science.

In addition, nearly 65 percent of children under the age of eight consume television programming for nearly 90 minutes everyday. The effects and influence of media are slowly shifting to other mediums such as the internet on mobile devices, making their usage more frequent throughout the day, which in turn is suspected to result in lower socialising and attention span disorders. Thanks to these ever-present devices, the attraction to mobile and console gaming, social media interactions and educational-based computer usage is on the rise since the last two years in households with internet access.

The core of these results aren't just correlative to technology use amongst children, but also indicative of certain affecting factors. While technology is observed to help enhance educational engagement amongst kids, this rule doesn't apply when children aren't supervised in its use. The tendency of children to use their computer during time allotted for other non-educational activities such as social networking, gaming and general entertainment is a major factor in the above stated results. This impact is more severely noticed in relatively lower-income households, where the burden of micromanaging young children is difficult to pull off by either parent.

Even admirable ventures such as the 'One Laptop Per Child' program, which have been enacted in many poor regions of the world, was indicative
