

explore the internet. The results have been very positive, proving that e-learning solutions need further exploration at every level through innovative thought.

This form of innovation in e-learning is necessary for the industry's social viability to be valid. The market for digital learning has been booming since the proliferation of personal computers. However, many of the solutions have been simplistic and temporary. The majority of the programs used in digital learning for young children have been games that help develop basic academic skills such as math, spelling and reading. These programs were distinct options on a PC back in the day and can now be found for free on the internet, but

they compete with a wider world of risky distractions. Since the methodologies of education, technology and culture are so intertwined, the mechanics of how children learn also differs from country to country.

Tech helps students to connect with teachers across the world

The refining of all these factors towards a unified understanding is necessary if businesses are going to market child-oriented e-learning, which in itself is a new beast, one that is still being finessed in India and the world.

Forecasts for the education sector

The projections for the current year anticipate the education market in India to reach almost \$110 billion in revenue. The market already witnessed growth of nearly 18 percent in 2013-2014 and then to over 50 percent in 2014. This trend points to the anticipated growth of a further \$40 billion by 2017. Globally, new regions such as Asia-Pacific and South America also follow similar trends and embolden these projections for 2015. In Asia alone, the e-learning market has witnessed over-the-top growth in countries like China, Vietnam and Malaysia, which make up a sizeable chunk of the global 30 percent that Asia represents.
