

linear editing is the process wherein a software allows users to edit digital video files in a closed environment without altering the original source file i.e. non-destructively. The non-linear aspect of the definition is in relation to the old analogue method of editing physical film prints which required a linear approach. This means that in order to access any specific part of the film/video an editor would have to “scrub” through it in a linear order from the first frame to the required frame. With nonlinear editing the digital metadata of the video files allows users to jump directly into and around any part of the video they wish. This process also makes the editing non-destructive since the original raw file isn’t altered in any way.

The way in which video editing software are used is fairly broad and can vary from the simplest output to a highly complex output. In its most basic form a video editing software allows editors to arrange images, video and audio files in a sequential order of their choice. All video editors, even the most basic ones such as iMovie and Windows Movie Maker allow for the arrangement of images, video and audio. The main difference between the basic and advanced platforms is the detail and intricacy with which they allow the arrangement. For example: if you have a series of photographs and videos, such as those from a party or vacation, and wish to simply lay them out in a particular order with a song underlaying it, then the simple video editors will do the job. But if you wish to shoot a small creative video where audio is varied in speed and pitch, shots cut back and forth at precise frames, the video has been custom adjusted

Adobe CC programs take traditional workflow methods and infuses them with modern technology.
