

meant that when we sat at the desktop to begin editing, all the iPhone footage was already imported and formatted as per our specifications remotely from the phone. Epically cool.

The next step was consolidating the footage in the two different editors. In this instance Adobe simply

Mobile device integration is the next wave of change in the world of digital editing.

allowed for a drag and drop start up with the footage while Lightworks required us to convert MOV format files into MPEG-4. We chose to convert all the files to MPEG-4 for Lightworks to retain consistency of footage. This took some time. In the meanwhile we had already begun editing with Premiere. The fundamental editing tools in both the programs performed as expected without any problems. Adding transitions was equally easy and without any significant difference. We were able to add images to both our edits without any issues. However, Lightworks didn't support the GIF image format. When it came to audio files Lightworks again proved choosy and only supported WAV and MP3. The in-built range of transitions and options was far greater in Adobe which was expected but Lightworks had sufficiently well stocked options as well. All other workflow features such as auto save, display options and title making tools were equally useful.

In the end Adobe proved to have more options in terms of its output options since as previously stated, Lightworks Free restricts users to only less than 1080p output. Both Lightworks and Premiere allowed us to author a DVD/BluRay publishing display which we could directly send to a DVD/BluRay device to burn our discs. Overall, it was obvious from the get go that Premiere Pro CC was going to perform excellently, but barring the conversion and file format restrictions, Lightworks' performed just as well albeit with fewer effects and transitions.
