

don't know what they want. You need to find out what even they don't know that they need.

3. You don't need to test a good design.

Granted, you may be talented, vastly experienced, and you know what you're doing. NO ONE is good enough to create a great design the first time around. Even if you got lucky, the users will change over time (as all humans do) and then you're out of luck. Testing is absolutely necessary!

4. UX design stops at the edges of the product.

You probably already know the magical feel of posh packaging. Extend that to things like customer service. That is all a part of the user's experience too!

5. Testing is done at the end.

Testing can be done at any time during the lifecycle of the product, even before the prototype is ready. Have your sketches and wireframes ready and head over to a few users and ask them to interact with your design while you simulate the outputs for their chosen input. Testing early helps catch potential errors as soon as possible, saving time, money and effort. It also helps the product evolve faster.

6. Be original with your Design.

While being original is a good thing, there are many advantages to using well-established designs. The design elements are probably the result of testing for usability and users may be familiar with the design and its layout if it is a popular convention. Also, nothing is truly original anyways, so don't try to re-invent the wheel.

7. People will use your design the way you thought they would.

It would be more fun to have you learn the folly of this thought from practice, but we are kind souls, we seek to educate. When users aren't clear on the prescribed ways to use your product, they will begin to use it in unconventional ways. Sometimes, they will use it unconventionally just because it was the only thing available that they thought could solve their problem. This is a good thing, embrace it.

8. UX Design is a step in your project.

Successful UX design needs to integrate the business goals (not necessarily
