

Wireframe, which is a visual schematic of the various pages or screens that the user can interact with, their key elements and also their hierarchy (Information design, Interface design and Navigation design respectively). It is discussed deeply in Chapter 5. The Wireframe, being a low-fidelity (possibly paper) prototype, roughly displays the arrangement of content, roughly demonstrates the interface, and roughly captures the navigational flow and information architecture of the website or application, although that is covered by the Sitemap later on.

A Comprehensive Sitemap

Actually, why save it for later, make the Sitemap in accordance with the Wireframe, since it is an essential deliverable that defines the information architecture of your application or website. Some Use Cases and Scenarios will help further refine the Wireframe, as they are meant to document detailed usage in every conceivable circumstance, making sure that no angle of product use is missed. Now for the first time, it is time for a Usability Test, which involves sitting with a User and asking them to perform tasks using the low-fidelity prototype (the Wireframe) and their imagination. You can ask them the most important questions that you can think of, and especially make note of the tasks they couldn't achieve. The feedback you get should be used to redesign the product by revisiting any of the previous steps if necessary. Next, create a higher fidelity prototype like a Mock-up, which
