

The first wearable watch, on the other hand, was worn in the 1500's as is evident from records of Queen Elizabeth had a wristwatch in 1571.

But in the technical sense of the term 'wearable technology', glasses were the first real wearables. Modern eyeglasses came about after 11th-century scholars happen to come upon the fact that the written word could be magnified by convex lenses. Those early observations led to affixing pieces of shaped, polished glass, namely lenses into two small frames so that someone with vision problems could have a chance to enhance or correct their sight. The handheld, temple-less design persisted until around the 1700s and eventually this initial design was discarded for the modern eyeglasses, the achievement of technology, that we cannot live without today.

The latest trends in technology lean toward gadgets that are built to augment and make our lives better. From the introduction of the Google Glass in 2012, to the buildup surrounding the Apple Watch; sleek, featureful devices that you can wear on your head (like a pair of glasses) or strap onto your wrist have become all the rage in tech jewellery.

Even more exhilarating are second-skin devices such as those that one can embed into the body, ingest and hear using. These may include new technologies that blend

into the skin, devices that are controlled using eyeball-motion sensors and ear wearables that measure and even respond to our heart rate and who knows what not. All of these contribute as a parts of the continuing journey to create technology that is so intertwined with our lives that it becomes almost imperceptible. The end results of this transition are bound to be better usability and genuinely groundbreaking technology.

The Good, The Bad and The Ugly of Wearables

With wearable technology, say hello to a time in which learning more about yourself has become high-tech along with being real-time. From gadgets and apps that help you track your heart and food consumption to devices that are capable of monitoring your mood and even the surrounding air. Now, the human body quantified, is a reality for the everyday person. We can look forward to the time in the near future where we can learn about our own health using our own self-tracking gadgets. Let's go as far as to imagine using these very devices to quantify if our self-improvement endeavours are actually paying off, all in real time.

One of the most critical elements of the adoption of new technology in question is getting the users and consumers at hand to change their habits.
