

Wearables will speed up the advent of Exoskeletons and even Prosthetics

Implantables

Implantables are devices that are surgically attached someplace under your skin. They are a type of wearable that one would have no choice but to carry around everywhere. They can be used for medical purposes like as insulin pumps, contraceptives or some of us just might enjoy sticking magnets to our fingertips.

The idea might sound a little bit futuristic and maybe even far fetched, but in reality, ingestible sensors and implantable chips are already in use and even growing.

Wearable Robotics

How does one person carry loads that takes two people to lift? Upto 68 Kgs even. The answer is wearable robotics. Wearable robotics lets us augment and compensate for our natural abilities.

In the past, wearing prosthetics or wearable robotics has been stigmatized but that is no longer true. It isn't just athletes wanting to be 'superhuman' using these high tech technology, it's also the average Joe with a sense of style and a preference among these new generation prosthetics. They are stylish, sleek and designed for an all round high tech lifestyle.

Taking hearing as an example, a hearing aid is what would help a person overcome a hearing deficiency. Wearing one in public would definitely mark you somewhat unfairly as someone disabled.
