

have some fitting app where you can try out stuff from their catalog by either uploading a picture of yourself or in real-time via your phone's front camera. IKEA even has an app that allows you to visualize how their furniture would look in your home against surrounding objects.

AR and wearables go together like peanut butter and jam. In fact, the first thing you think of when you think AR must surely be either Google's Glass or Microsoft's HoloLens—two pioneering devices in the context of making AR mainstream. Both devices enhance the user's everyday visuals by providing contextually important information on the wearable head-mounted display. Glass was designed more towards the lines of a smartphone supplement (much like wearable smartwatches), whereas the HoloLens is more of a standalone device, although it can be paired with Windows smart devices for better inter-device control.

This sort of an immersive user interface has numerous applications by increasing productivity at work and home. The ease of use this interface offers, not the mention the sheer novelty factor, has made the tech community extremely excited about its eventual assimilation into mainstream computing. During a recent Windows 10 press conference, Microsoft teased a video in which a HoloLens uses built a model UFO using virtual images shifted around in midair. This idea could be expanded to build plans for skyscrapers, vehicles and other feats of engineering in seconds using virtual schematics.

The Think Tank Team—headed by Pranav Mistry who is also the Director of Research of Samsung Research America—is developing an AR based wearable known as SixthSense. Similar to HoloLens, SixthSense is focused on integrating real-world objects with digital information and virtual objects. The device is made up of a camera and projector pair, worn very much like a tie, with the camera located at the neck region and the projector placed right around the region between the chest and stomach. The camera is used to detect four colored rubber bands tied around the tip of your index and middle fingers on each hand. The motion and gestures made by your fingers in translated to input for the visual interface output by the projector on a nearby surface.

This technology is perfectly exemplifies the capacity of AR and its communion with wearables. Potential applications for SixthSense include making the photograph gesture with your fingers to instantly capture an image, scanning book covers and displaying relevant information melded with the cover image and text, scanning boarding passes and displaying
