

time before our smart devices not just recognize what we say, but predict what we are going to say and act on our thoughts before we do.

Brain–Computer Interface

It is a known scientific fact that our brains generate electrical signals using cells known as neurons. In fact, almost all of our thoughts have a unique brainwave pattern, which are detected using a method known as Electroencephalography or EEG. This method uses (in most cases) non-invasive electrodes placed strategically across the scalp that measure voltage fluctuations resulting from ionic current within the neurons of the brain.

Scientists and doctors have used this method to map brain patterns with specific commands and actions. This technology has tremendous potential in terms of interacting with wearable devices, especially those designed to augment accessibility for physically handicapped people.

Research programs dedicated to developing similar brain-controlled interfaces have been accelerated of late with additional funding. One of the
