

Navigate left to right and back, walk or do whatever you want, the way a simulated medium responds will show how interactive it is. With VR, the interactions should be crisp and quick.

3. Artificiality

Artificiality can be called as 'reality or actuality of the artificial' medium. To create artificiality, the environment has to be manipulated and made similar to the real world. And VR does exactly the same - it puts you in a world which is imaginative and yet seems real.

4. Immersion

Now that the imaginative world is created, how do you think a person can enter inside it? That's when certain hardware and software comes into the picture. With data gloves, optical devices, head trackers and hand-held objects a user perceives to be in a virtual world. This sensory involvement is called Immersion. Interaction and immersion is interlinked.

Virtual Interface Environment Workstation (VIEW) - A virtual workstation of NASA in which the user immerses into the system wearing data gloves, data suit and an eye phone. This increases the level of simulation for virtual reality and the computer registers wearer's bends, gestures, motions and spatial direction. The user could manipulate the happenings on Mars while being on Earth.

Thirty seconds to mars... Virtually of course.
