

mathematics, first developed the technology for Leap motion. His vision was to create a controller-less interface to VR to make it feel much more natural. In 2010, he co-founded Leap Motion Inc. with childhood friend Michael Buckwald.

Simply speaking, The Leap Motion controller is a complex motion sensor. With 2 monochrome IR cameras and 3 infrared LEDs, the action area for the controller is a rough hemisphere with a radius of about 1m above the device, as the device faces upwards. Infrared light generated by the LEDs is reflected off the hands placed in this area. This reflection is then captured by the cameras at almost 300 frames per second and the data is sent via USB to the connected computer, where it is processed by the Leap controller software to generate positioning data in a 3D space by

The Leap motion controller : to the unaware, it might appear to be a fancy flashdrive

comparing 2D information from the two cameras. Due to the smaller area involved, the controller is capable of extremely accurate motion tracking and movement detection.

After a number of funding rounds, their first product, the Leap, was announced no earlier than 2012. Along with that, a software developer programme was also launched with distribution of roughly 12,000 Leap devices to create a vibrant app ecosystem, although eventually the sale volume in the first year post it's 2013 launch was not as expected.

Currently the company is focusing more on integration with VR headsets and mainstream PCs and laptops. Several HP and ASUS laptops are set to ship with Leap Motion inbuilt into them. The true innovation in using Leap Motion with a VR headset like Oculus is well shown in this Large Hadron Collider simulation covered here - <http://dgit.in/ColliderOR>
