

The strongest point in favour of PSVR is its integration with the PlayStation platform

The One Glove to feel them all

What would it feel like to touch something that is not really there? That question doesn't have to be unanswered any more, thanks to Spain-based NeuroDigital Technologies. Their brainchild, the Gloveone, is a haptic feedback glove that can let you experience sensations in virtual reality, such as rainfall, heat, weight, shapes etc. This is essential in closing the VR experience sphere to make it as lifelike as possible.

The glove has strategically placed sensors on the thumb, index and middle finger as well as the palm, that can interact with each other to coordinate a sensation. It uses 9-axis inertial measurement unit sensors, which are typically used in aircrafts to measure gravitational force and velocity. For the feedback, the glove uses 10 actuators placed on the fingertips that vibrate when a touch action is registered in the VR. This generates the accurate sensation of touching by vibrating at a wide range of frequencies and intensities. The glove also has special areas which act as buttons in response to touch.

Their kickstarter campaign was started in June 2015 and achieved its target of \$150,000 by mid-July. As of now, you can get yours in the 2nd quarter of 2016 by pre-ordering it from the official Gloveone store for approx
