

Rift. What is exciting is that, it supports 4 simultaneous users at a time in one environment. It also has USB Audio support and comes with fast charging and a maximum 20W/h power consumption at full use. Best part? You can carry it in your backpack. Check out their products page at <http://digit.in/NefesVR> for more details, along with some other impressive products like their own HMD project and a wearable graphics module.

One of the most important companies working in this space is Nitero, makers of the NT4600. It is a 60G (yeah, not 6G, it's actually 60G) wifi mobile chip that promises to be the perfect support for modern 4K phones with near zero latency. The company has shifted its focus towards VR with an aim to develop and demonstrate a near-zero latency connectivity solution for VR by the end of the year. Their approach combines their own 60Ghz wireless transfer technology along with video compression. Even though their work is at a nascent stage on this, the company assures that their technology will work with 8K VR and beyond. The key specifications are as follows:

- ◆ Latency “in the order of 100’s of microseconds”
- ◆ Configurable compression ratios from 4:1 to “>16:1”
- ◆ 4.6Gbps Data Rate
- ◆ 3.5Gbps Effective Throughput
- ◆ Non Line of Sight, Multiplayer
- ◆ Power “as low as” 500mW

A much more complete solution right now is the Auravisor, a fully self controlled VR headset that requires no computer or smartphone whatsoever. It has an on board android computer and a wide variety of apps on its store that is based on, and linked to, the Google Play Store. It achieves its functionality via high speed wifi on board. It provides 1080p resolution on a 5” screen and supports audio out and external memory cards. The lenses and depth of field are adjustable and multiple faceplates are available to use. All of this, for roughly 260\$. Their stretch goals include, among other things, hand gesture recognition. We hope it can detect our fingers crossed gesture.

VR doesn't like to Move it Move it!

Even if we may soon have slim, wireless HMDs within reach, what happens when we go chasing after that virtual rabbit? Yes, a real intervention in the form of our living room wall happens. One of the biggest gaps between virtual reality and the real world is moving around as far as you wish, as fast as you wish, in any possible direction. The Virtuix Omni is
