

as easy as saying it. Making a VR headset that works well requires a good knowledge of sensors, displays, computer graphics, optics, programming, ergonomics, networking and some other fields that we may have missed. Needless to say, these requirements create a significant entry barrier, which when combined with the pricing of high grade sensors, lenses, processors and interactable components, drives up the monetary barrier as well.

What this field requires, is time. With technology, we are too accustomed to overnight successes and groundbreaking advances everyday. But this field is so entirely new and different from whatever we have done so far, it needs to be approached cautiously, so as to not hit industry wide roadblocks. We need to have sufficient opportunities and time to innovate and experiment before markets are flooded with a particular product. As with all the other fields, democratization will only break the entry barriers and bring VR to the masses. Not just nausea inducing, cardboard-ish VR, but high quality TrueVR that feels “sick”, and doesn’t make you feel the same.
