

An ideal use case of Virtual Reality

uted to Virtual Reality. In contrast to AR, Virtual Reality focuses solely on a virtual world which is artificially simulated using a projection device. This projection device can be a head mounted display or a larger space like a completely enclosed and simulated pod. It is essential to note that VR does not intend to interact with the real world, the only purpose of VR is to engage users, by the use of its projections and their senses.

Since Augmented Reality and Virtual Reality are technologies that are ambiguously related, they share a very common history of growth and development at the initial stages which can be traced back to 1950-60s when head-mounted displays were just being introduced to generate simple wireframes of virtual models of the physical world. Nonetheless, it paved the way for Virtual Reality and eventually led to the development of Augmented Reality. While Augmented Reality was also popular as “an ambiguous idea inspired from virtual reality”. The actual term was coined by Tom Caudell in 1992. Evidently, it was Virtual Reality that sowed the seed of Augmented Reality and not the other way round, as per some misconceptions. Since then there has been no turning back and Augmented Reality has slowly crept its way in. From times when it was just used by major companies
