

Virtual consultations and treatments are slowly catching up

addition to gaming, there are numerous other sub-domains such as virtual theme parks, concerts, performances and many more.

Another domain that has majorly garnered the attention of these technologies is science and medicine, with a precise focus towards research and innovation labs. These labs use Virtual Reality to simulate virtual test cases and may later perform operations and experiments on these test cases using Augmented Reality. Even though scientific labs remain the major consumer of the technology in this domain, the healthcare industry has caught up with the advancements. Remote surgeries are being made possible by simulating the cases using Virtual Reality and doctors might often use Augmented Reality to get the feel and look of the patient's case.

How do AR and VR systems relate to each other?

It is evident that AR and VR share the same gene pool and it might seem that they are inherently similar to each other, but if that would have been the case why did we bother to think of different names for these two technologies? Even though these technologies may seem similar at the surface, if we look underneath the covers we will find them to be significantly different. The very basic purpose of both the technologies differs a lot. Virtual Reality aims
