

The major hurdle for VR to overcome is that the technology required to simulate such an immersive experience has remained elusive. Any system that provides an immersive experience will require some sort of display that will try to fool the human into believing that the virtual system is real. Such systems can be problematic to use, largely because skilled labor and technical knowledge are required to repair or maintain them, which is hard to find. It's not just the implementation that is a problem, but the after effects may also be an issue. A major negative effect that a VR system can

Interactivity and Simulation are major hurdles in an AR system

have on its end user is simulation sickness. Patients with a fear of heights or cardiac diseases are always advised to be cautious while interacting with a VR system.

On the other hand, AR as a technology faces issues due to its high interactivity with the surrounding and the simulation of the real world.

The prime issue faced in an AR system is the limited field of view of the projection gear. Hence, an AR system cannot augment an entire sphere of view because such a technology is still primitive or illusive. Whatever success that has been achieved in the field of AR till now can be attributed to avant-garde technology. But such a technology involves a large overhead of processing and maintenance. An AR system generates tons of data from its cameras and sensors in order to gauge the surroundings. Hence, complex databases are required to store and process this data, which involves a huge expense on the data storage front since all the minute details are required to be stored. But the problem is not just limited to storage, AR systems
