

require lightning fast processors in order to minimize the response time for fetching data thereby reducing projection latency.

A burning issue around the alleys of technological innovation is the utility of AR when coupled with advanced image recognition algorithms. If we pursue this use case of Augmented Reality, it will soon let us recognize people by just pointing our cameras to them, which would in turn fetch data about the user from their public accounts and generate a complete profile using the information that has been collected throughout. Though such an application might promise leaps of success, a probability of such a future has raised serious questions regarding the privacy and security issues of Augmented Reality.

Sophisticated AR along with high-tech image recognition can invite unwarranted troubles.

Popular devices in the tech-culture

Numerous tech-giants have jumped on to the AR and VR bandwagon since the technology is still in the primitive stages and is yet to strike the masses at large. Almost every technology company is associated with these technologies directly or indirectly. Companies like Google and Microsoft are leading the brigade with front end devices with no less enthusiasm from startups to overturn their supremacy, while some companies are venturing into the domain by acquisitions, fundings or mergers.

Google Glass is the most popular and widely known AR device, which is an optical head-mounted projection display, worn like a pair of glasses. It is an augmented reality headset that assists and helps the user in day-to-day chores. Even though Glass had caught the initial buzz amongst enthusiasts, it was eventually shut down due to multiple issues including privacy
