

"A camera gesture" - Instructs the camera to take picture defined by the boundary of the fingers. Sixth Sense uses such hand gestures to operate on predefined operations.

using a neck worn or head worn cameras, which are used to interact with the user as well as the surrounding objects. The central idea behind Sixth Sense is to recognize gestures using specific signals from the user such as ambiguous shapes or colors that are pre-defined to trigger an action at the processor. The main advantage of Sixth Sense technology is that it is open source and cost effective, hence, it encourages developers and designers to add features to the existing product economically, which is unlikely to happen in a proprietary hardware such a HoloLens.

Future scope and the possibility of a brighter tomorrow

The future of both AR and VR looks promising though both technologies have a lot of scope for improvement. For starters, devices in both the domains will shrink significantly and offer more and better processing power with time, which is in accordance with the Moore's law. Forbye size, the gadgets of future can be expected to be less clumsy and will have a better immersive experience. On similar lines, bionic contact lenses are being developed to
