

Augmented Reality vs Virtual Reality

In a practical world, it is not always virtual reality v/s augmented reality – since these two technologies might not always be mutually exclusive, and in fact, might be tightly woven together to generate an even more immersive and engaging experience. For example, haptic feedback i.e the vibration and sensation can be added to interaction with the VR system – which can be considered as an augmentation in the virtual world. Virtual reality and augmented reality are extraordinary examples of experiences and interactions nurtured by our desire to immerse in a simulated environment, or to augment the interaction between digital devices and the real world. Whether these technologies work alone or together, they are undoubtedly paving the way for the future of both – enhanced real world and super simulated virtual world.
