

of smaller robots that can form components of a much larger structure allow us increased control over its functioning, and it is only a matter of time that this gets used to create the body that will be one side of the output of the VR experience.

On the other side, the same small robots can allow us to create VR products that will encompass the entire human body, generating an extremely accurate sense of touch and temperature. Think of it as a full body Dataglove. Even if the other side of the experience does not have a dummy body being controlled, increasing the degree of interactability will only make VR seem more real. Holographic projectors around the room could be projecting a 3D hologram surrounding the user, while high-accuracy sensors around the room detecting each movement by the user. The floor could be an omnidirectional treadmill allowing free movement. There could be smell emitters around the room that would generate the correct scents based on the environment being played in. Or we could simply not do all of this.

Matrix was perhaps the most iconic VR movie ever. So it is not surprising that we seem to be visualising one particular version of the future where we are using the most powerful VR controller ever possible - the brain. Everything we experience in our reality is made up of electrical signals in the brain. As a result, if technology could be able enough to create a device that would be able to connect to the brain and trigger those signals based on external inputs from a computer perhaps that would be the birth of absolute VR. And we all know it very well, that any 'if' in technology is a 'when' in disguise.

There is an even more advanced perspective that might not be too unreal, in spite of the philosophical questions it raises. When anyone got disconnected from the Matrix abruptly, they died in the movie. A certain section of the science world believes in the possibility of mind uploading, even to a virtual reality. This would require immense research and near infinite computing capability, but with quantum computing already being achieved, is this possibility really that impossible to accept?

A Day in the Life of V.R.Joe

Barring the extremely advanced perspectives of mind uploading or VR through a brain, it is quite evident that most of the technology visualised in the previous chapter is rushing into our lives faster than we expected. Pretty soon, maybe in about 10-20 years, our lives will be completely entrenched in using VR for a lot of things. Let us have a look at the life of V.R.Joe, our everyday guy in the VR Future:
