

Moreover, these panels have a much higher contrast ratio of 5000:1 making them an all-rounder of sorts.

PVA

Super PVA (S-PVA)

Introduced in 2004, S-PVA was simply an reproduction of how S-MVA was to MVA. Overdrive helped reduce response times and the liquid crystal structure was modified to look like a boomerang. This was said to help improve viewing angles and colour reproduction.

cPVA

In 2009, Samsung's next iteration of the PVA panels were called cPVA. They had a much simpler sub-pixel arrangement than S-PVA which helped reduce production costs. The sub-pixels had a more uniform brightness and didn't seem to impact gamma or colour tone shift.

Advanced-PVA

Samsung has been quite secretive about their panel technologies and in 2012 they started labelling their PVA panels as Advanced-PVA or A-PVA to distinguish them from the previous generation.

Super VA (SVA)

Again in 2014, Samsung started calling their PVA panels as SVA (Super-VA). They happen to be the only mass-produced PVA display panels on the market. The latest curved VA monitors and televisions supposedly have these under the hood.

Pros and Cons MVA

Pros

- ◆ MVA panels have very high contrast ratios. Typically greater than 3000:1
- ◆ Current gen MVA panels

WHY DOES VIDEO CONTENT ON DISCS LOOK BETTER THAN STREAMING CONTENT?

Full HD content on a Blu-ray disc appears much better than the same being broadcast through satellite TV or streamed through YouTube or Netflix due to the limiting factor of bandwidth. Discs hold a lot more storage space and can therefore be generous with the bit-rate at which the video content is encoded. Video on discs is compressed far lower compared to the same being streamed, which makes for better quality.
