

type of monitor that is purchased is a type of TFT LCD display. So let's take an in-depth look at what makes IPS stand out from the crowd.

Why was IPS needed?

TN panels were and still are a popular choice of panels for display makers and 75 percent of almost all displays produced use TN panels. They are cheap, offer great response times and essentially is worth every penny. But then one could wonder that if these were so popular would there be any need for other panel technologies?

The answer is very simple, you can't get the best of everything for cheap. TN panels though snappy with excellent response times which can be as low as one millisecond have horrendous viewing angles. This means the tone of the colour observed by the viewer changes drastically with change in viewing angle. But that's not the case with IPS displays. The modern day IPS display can have as much as 178 vertical and horizontal degrees of viewing angle. But if you are going to ask us where did the last two degrees go then we really have to ask you: 'Are you going to be perched on the display and look down at it', because that's the only plausible scenario for having benefits of a 180 degree viewing angle.

The viewing angle debacle
