

- ◆ Blackening is a defect most commonly found in VA panel billboards and occur when the display is exposed to sunshine for prolonged periods.
- ◆ Stress endurance or touch flash resistance of IPS panels is greater than VA or TN panels. We might all have noticed at some point that the image on our displays smudges over when a considerable amount of force is applied. That's the result of high image retention and low panel endurance.

Touch flash IPS panel vs VA panel

Cons

- ◆ Pixel response time has never been a strong point of IPS panel. The reason simply being their mechanism of working. The parallel alignment of LC can reproduce better colour gamut but at the same time it also increases the obstacles in the path of light propagation. Response time for IPS panels are typically around 8-10 milliseconds, this is going to affect your game play. Especially if you like playing fast paced genres like FPS games.
- ◆ IPS panels are very costly to begin with, and if you want a display with faster response time then you are going to have to pay another premium in addition to what you are already shelling out.
- ◆ IPS displays have a pair of transistors powering the LCs so they tend to consume more power compared to other panel technologies.

Chronology of IPS

- ◆ **super TFT (IPS)**- Produced by Hitachi in the late '90s, this is what began
