

making its flexible display panels using hybrid glass, to make OLED TVs and smartphones fully commercialise by the year 2020.

Fujifilm has shown a keen interest in developing OLED panels and in this research phase of Fujifilm, they have managed to create an OLED array of 640 ppi and have a bead on hitting 1000 ppi.

BMW, the luxury car maker is also experimenting the use OLED pixels for lighting the interior of the cars and use OLEDs for the braking and indicating lights, but they seem to be dimmer than usual, for now.

Would it be safe to say that the future TVs and monitors will use OLEDs or is it just a stepping stone for stepping on to the next, bigger display technology that might be on its way? Was high production cost the reason that Samsung invested out and went back to LCDs, developing the quantum dots technology, or was it the low yield of OLED panels and the lack of durability and a definite future? The ultimate question that arises now is that how far are we from the OLED era, and that is if there will be one.
